What You Will Learn Many large buildings, campuses, and other facilities have plants that make chilled water and distribute it to air-handling units (AHUs) and other cooling equipment. The design, operation, and maintenance of these CHW plants has a very large impact on building energy use and energy operating cost.

system shall be utilized wherever possible. The district cooling system is comprised of four major subsystems; the production system, the distribution system, the building bridge system, and the building cooling system.

Designing chilled water systems Typically used for cooling and dehumidifying a building's air, chilled water (CHW) systems circulate it throughout a building or campus complex. CHW systems also may be used for removing process or other heating loads. By Randy Schrecengost, PE, CEM, Stanley Consultants, Austin, Texas September 16, 2014

The chilled water is generated and circulated in the primary side, the secondary loops will pull chilled water out of the header to cool the building and then dump the warm return back into the header. If the flow rate in the secondary side is low then some chilled water will flow into the secondary and some will recirculate back to the chillers.

Chilled water systems include other HVAC equipment designed to exchange heat such as computer room air conditioners. The chilled water absorbs the heat from the building. It then returns to the chiller where the chiller removes the heat from the water using the refrigeration process.

~~Chilled Water System Basics [HVAC Commercial Cooling]~~

A simple chilled water cooling system configuration can consist of a single chiller and a single pump. A more complex chilled water cooling system configuration can consist of multiple chillers, multiple pumps, cooling towers, heat exchangers, and all sorts of valves to redirect flow according to the heat load inside of the building.

This minimum rate, which can be obtained from the manufacturer, will vary with design chilled water flow rate and the chiller type, size, and manufacturer but is typically 25% to 50% of the design flow. A VFD is shown in. Figure 2. ; VFDs are typically cost effective except on very small systems.

Chilled water systems work on the same principle as other air conditioning systems that use standard refrigerant, but are mainly found in industrial settings because it costs less to use water for cooling. It's also more efficient to run water pipes over a large commercial area, with the pipes distributing the water to evaporator coils in air handlers, than it would be to run refrigerant lines.
