This tutorial shows how to use dependency injection (DI) in .NET. With Microsoft Extensions, DI is a first-class citizen where services are added and configured in an `IServiceCollection`. The `IHost` interface exposes the

Dependency Injection (DI) is a pattern that can help developers decouple the different pieces of their applications. It provides a

Dependency Injection (DI) is

a design pattern, using DI we can keep dependent objects outside of the class that depends on them, we can achieve loosely coupled design with the help of DI.

The Dependency Injection is a design pattern that allows us to develop loosely coupled software components. In other words, we can say

that this design pattern is used to reduce the tight coupling between the software components. As a result, we can easily manage future changes and other complexity in our application.

Constructor injection is by far the most used type of Dependency Injection.

Dependency injection is built in ASP.NET Core, and we're encouraged by the

Actually, we might even find it hard not since it's deeply integrated into the framework. But let's put all this theory to practice.

The Dependency Injection (DI) Design Pattern At a high level, the goal of Dependency Injection is that a client class (e.g. the golfer) needs something that satisfies an interface (e.g.

What is Dependency

Injection? A dependency is any object that another object requires. For example, it's common to define a repository that handles data access. Let's

Dependency Injection: In
software engineering,
dependency injection is a

technique whereby one object supplies the dependencies of another object. In other words, we can say that, it is a coding pattern in which classes receives their dependencies from external sources rather than creating

them itself.
